

**MET CS 699 Data Mining Project**  
On Final Report of the Asian American Quality of Life

Philip Chang, Min Cheng

## 1. Statement of Data Mining Goal

The U.S. Census defines Asian Americans as individuals having origins in any of the original peoples of the Far East, Southeast Asia, or the Indian subcontinent (U.S. Office of Management and Budget, 1997). Currently, in the U.S, 18.64 million Asian Americans represent 7% of the nation's overall population in 2021. The number is projected to surpass 46 million by 2060. ([Pew Research](#))

Asian American community is a unique community that is diverse in culture, yet shares many similarities within. As Asian American population exponentially grows from minority to majority, we wish to better understand the current social and health state of the community.

Our goal in this project is to predict Asian Americans' satisfaction level with their overall "Quality of life", which is also our class attribute, based on different attributes. There are many attributes such as housing, salary, family ties, religion, and ethnicity which would help us better understand what are the driving forces of Asian Americans' quality of life.

## 2. Detailed description of the dataset

Our team's dataset was the Final Report of the Asian American Quality of Life (AAQoL), a compiled individual survey which was conducted on Asian American population in the city of Austin, Texas.

Survey questions were divided into answers to 7 different sections: Demographic, Immigration and Acculturation, Health, Special Interest, Social and Community Resources, Life in the City of Austin. The original dataset consists of 231 columns and 2,609 tuples of Asian Americans' survey results, including attributes like Age, Gender, Ethnicity, Marital Status, Education Status, Household Size, Religion, Employment Status, Income, English Level, Family Connection, Transportation Modes, and more. Each 2,609 unique survey represents an individual's information, which can be used for attributes determining the quality of life. Considering the design of the survey, the dataset mainly consisted of nominal and ordinal data.

The full list of attributes and the corresponding descriptions are in the link below.

<https://data.austintexas.gov/City-Government/Final-Report-of-the-Asian-American-Quality-of-Life/hc5t-p62z>

## 3. Brief description of data mining tool(s) used

Various tools were used for different purposes throughout the project.

Once the data has been extracted from the source, our team used R for the Data Preprocessing task. We have dropped unnecessary attributes, such as the 'Other'

sections, where surveyors would input character values for further explanation. R was used to detect any missing values, noisy data, and inconsistencies between variables. Outlier detection has been conducted using R as well. Finally, once all cleaning and prepping have been completed, we split the data into training and testing with R.

For attribute selection tasks, we utilized Weka. Weka provides easy access to various attribute selection methods. For model building and testing, performance analysis and visualization, we used Weka.

#### 4. Brief description of classification algorithms you used.

We built 5 different models to predict our class attribute(Quality of life):  
Naive Bayes, SimpleLogistic, Bagging, ClassificationViaRegression, RandomForest

- **Naive Bayes** is a Bayesian classification model with the assumption that attributes are related to each other. This model attempts to calculate the probability of class membership. This is a simple but powerful model comparable performance with decision trees and selected neural networks.

$$P(\mathbf{X}|C_i) = \prod_{k=1}^n P(x_k | C_i) = P(x_1 | C_i) \times P(x_2 | C_i) \times \dots \times P(x_n | C_i)$$

- **SimpleLogistic** is a classifier for building linear logistic regression models. LogitBoost with simple regression functions as base learners is used for fitting the logistic models. The optimal number of LogitBoost iterations to perform is cross-validated, which leads to automatic attribute selection.
- **Bagging** or bootstrap aggregating model averages the prediction over a collection of classifiers. This model is an ensemble method and provides significantly better accuracy than a single classifier derived from the dataset.
- **ClassificationViaRegression** is a class for doing classification using regression methods. Class is binarized and one regression model is built for each class value.

$$f(\mathbf{x}; \hat{\mathbf{w}}) = w_0 + \mathbf{x}^T \hat{\mathbf{w}}_1,$$

to classify any new (test) example  $\mathbf{x}$  according to

label = 1 if  $f(\mathbf{x}; \mathbf{w}) > 0.5$ , and label = 0 otherwise

- **Random Forest model** is also an ensemble method that builds multiple trees, and each tree classifies a given sample. This model is usually less susceptible to errors and outliers, handles unbalanced data well, and overfitting is not an issue.

Because only a subset of attributes is considered at each node, it is faster than most models.

## 5. Brief description of attribute selection methods you used.

We used 5 different attribute selection methods:

CfsSubset, Correlation, WrapperSubset, OneR, InfoGain

- **Correlation-based Feature Selection (CFS)** subset is an algorithm that couples this evaluation formula with an appropriate correlation measure and a heuristic search strategy ([Waikato](#)).
- **Correlation** evaluates the worth of an attribute by measuring the correlation (Pearson's) between it and the class. Nominal attributes are considered on a value by value basis by treating each value as an indicator. An overall correlation for a nominal attribute is arrived at via a weighted average.
- **WrapperSubset** method wraps a classifier in a cross-validation loop: it searches through the attribute space and uses the classifier to find a good attribute set. Searching can be forwards, backwards, or bidirectional, starting from any subset. Cross validation is used to estimate the accuracy of the learning scheme for a set of attributes.
- **1R** or One Rule is a simple, robust and efficient classification algorithm that generates one rule for each predictor. The goal is to make rules based on a single attribute. The algorithm chooses the minimum-error attribute as the rule.
- **InfoGain** Evaluates the worth of an attribute by measuring the information gain with respect to the class. In other words, this method measures how each feature contributes in decreasing the overall entropy.

## 6. The set of attributes selected by each attribute selection method.

## 7. Detailed description of data mining procedure.

Our team followed a full testing process of the selected models, described in the Diagram below.

**Full Process Diagram**

## 7.1 Data Preprocessing

- **Step1.** Checking for Missing Value  
We removed NA values on the surveyor's demographic information.
- **Step2.** Encoding categorical data  
The "No.One" column is categorical data with 2 levels, "living with no one" and "0", we encoded it into "1", "0".
- **Step3.** Checking for Inconsistent data  
We removed inconsistent data of "household size" and "living with no one".
- **Step4.** Checking for Outliers  
6 people over the age of 80 are detected as outliers. 2 Surveyors with duration of residency over 50 years are detected as outliers. We decided against excluding age as a factor of outlier detection and removed outliers detected with Duration of Residency.
- **Step5.** Data Reduction  
Because this is survey data, many entries are not subject to mining. These surveyor inputs are unnecessary, and therefore dropped.
- **Step6.** Reformatting the class attribute  
We reformatted the class attribute "Quality of life" to factors with wider bin size.
- **Step7.** Splitting the dataset into the training and test set
- **Step8.** Data formatting and export

## 7.2 Attribute Selection

With the training and test dataset generated, our team then moved to the attribute selection process. In this process, as our Process Diagram shows, we ran all 5 attribute selections in Weka on the training set generated. Each training set with selected attributes were separately saved.

## 7.3 Model Generation

With the reduced training dataset of selected attributes, our team started generating 5 models selected from above 5 classification methods. Once the model was generated with each of the 5 reduced training dataset, we tested out models with a corresponding test dataset with the same attributes.

## 8. Data mining result and evaluation:

Conclusion: According to the performances of 25 classification models below, we concluded that using **WrapperSubset** attribute selection method and **RandomForest** classification algorithm generates the best model. (*Accuracy = 78.0679%*, *ROC Area = 0.921*, *PRC Area = 0.874*) PRC Area has been used to evaluate the performance along with ROC Area, given that the dataset is unbalanced.

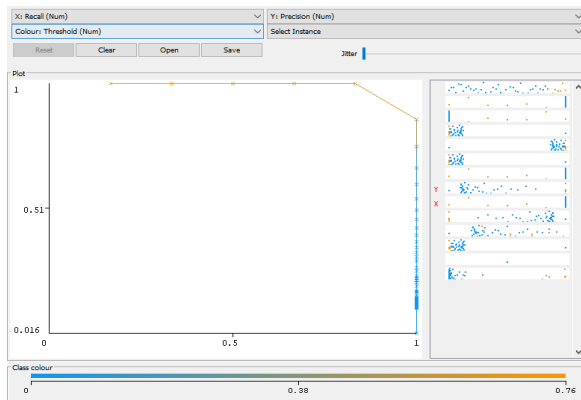

As we can see in the Curves below, for each class, the predicted class has been mostly accurate, especially for the lower ratings for quality of life.

*ROC Curves for each class*

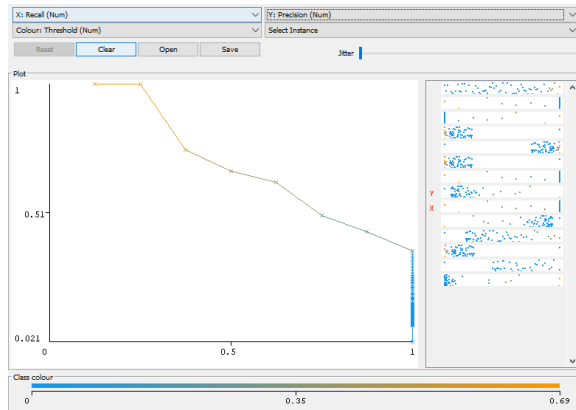

## PRC for each class

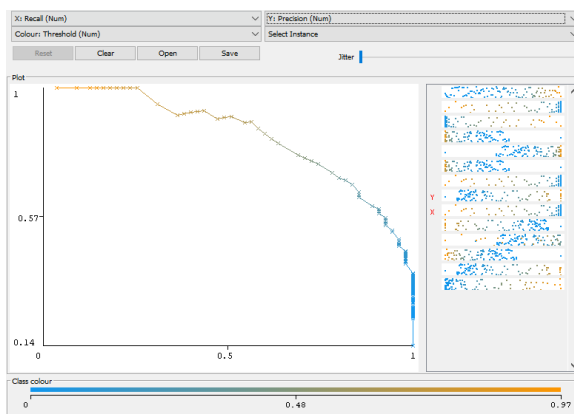

### Class1

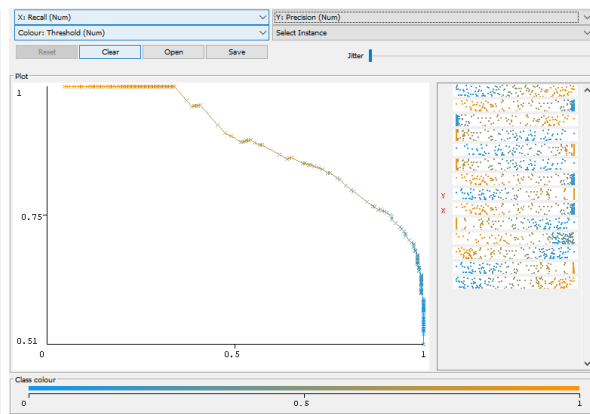

### Class2

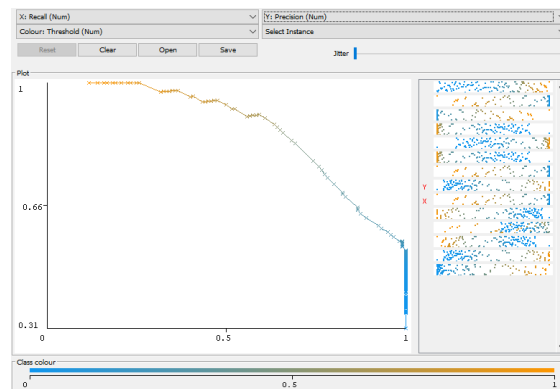

### Class3

### Class4

### Class 5

One of the reasons the Random Forest model performs best is because of the unbalanced nature of the dataset. Random forest tries to minimize the overall error rate, so when we have an unbalanced data set, the larger class will get a low error rate while the smaller class will have a larger error rate. Random Forest model builds multiple decision trees and merges them together to get a more accurate and stable prediction. It is also worth noting that the Random Forest model works with subsets of data, and thus works well with high dimensional data.

### Performances of 25 classification models (test dataset)

## 8.1 Results of testing models on reduced test datasets:

- Reduced test dataset1: CfsSubset

## 8.2 Comparison of the performances of the best model with the model that was built using the same classification algorithm from the dataset with all attributes.

The best model (using WrapperSubset attribute selection method with 8 attributes selected and Random Forest classification algorithm) performed (*Accuracy = 78.0679%, ROC Area = 0.921, PRC Area = 0.874*) better than the model with all attributes (*Accuracy = 61.8153%, ROC Area = 0.776, PRC Area = 0.647*). The TP rate of the best model is 16.2526% higher than another one.

Best model with 8 attributes

The model with all attributes (121 attributes)

## 9. Discussion and conclusion, including what you learned from this project.

### 9.1 Methods to increase performance

To increase the performance of our classifier models, several methods have been proven to be useful in our project:

- Removing inconsistent data and any outliers
- Reducing dataset
- Encoding the class attribute  
Encoding the class attribute "Quality of life" from "1-10" to "1-5" roughly increased 20% of the model accuracy.

### 9.2 Findings of the testing results

- Generally, the datasets with attributes selected using WrapperSubset method generated better performance, 5%-20% higher accuracy than other four attribute selection methods (CfsSubset, Correlation, OneR, InfoGain);
- Random Forest algorithm generates the best TP rate for Correlation and WrapperSubset test sets.
- Compared to other attributes selection methods, WrapperSubset selected the least number of attributes (only 8 attributes), so we conclude that less attributes contributes to better performance.
- Apart from the Random Forest classification algorithm, the bagging algorithm performs better than most other classification models. For test sets of CfsSubset and OneR, bagging generates the highest True Positive rates.

### 9.3 Suggestions for the future steps

- Based on the selected attributes using WrapperSubset, attributes including Present mental health, Satisfaction with life, Family pride, Library internet access, Citizenship class, Contact city official or not, City election, we found that people caring more about the city life and participating in local political activities seems to be important factors in quality of life. Contrary to what we believed, mental health and state were a bigger factor in quality of life than physical health or condition. These findings should be taken into account for future study.
- For the dataset(after preprocessing) using Correlation attribute selection method, we found that attributes like Satisfaction.With.Housing( $p = 0.1536$ ), Satisfied.With.Life.2( $p = 0.1416$ ), Achieving.Ends.Meet( $p = 0.139$ ), Satisfied.With.Life.1( $p = 0.1358$ ), Duration.of.Residency( $p = 0.1349$ ) have weakly relationship with the class attribute "Quality of life." To better understand what factors influence Asian Americans' quality of life, further research can be taken

on exploring its correlation with peoples' satisfaction with housing, achieving ends meet or not, and duration of the residency.

*\* We do all the work of this project together while Philip contributes a little bit more on R and the first half of this report, and Min contributes a little bit more Weka and the second half of the report.*
